

# Use SQLite and PHP

XAMPP comes with built-in support for SQLite, making it easy to get started building database-powered applications with PHP. This guide will walk you through the process of creating and populating a new SQLite database using XAMPP, then accessing the data within it using PHP.

Begin by creating and populating a new database using the SQLite command-line client, as below:

1. Open a new Linux terminal.
2. Change to the *htdocs/* subdirectory of your XAMPP installation directory (typically */opt/lampp/*) and create a new SQLite database file named *mydb.sqlite3* with the SQLite command-line client:

```
cd /opt/lampp/htdocs
/opt/lampp/bin/sqlite3 mydb.sqlite3
```

You should now see an SQLite prompt, as below:

A screenshot of a terminal window with a dark background. The prompt is `/opt/lampp/htdocs$ /opt/lampp/bin/sqlite3 mydb.sqlite3`. The output shows the SQLite version `3.7.17 2013-05-20 00:56:22`, instructions to enter `.help` for instructions and SQL statements terminated with a semicolon, and the `sqlite>` prompt.

**NOTE**

In case your user privileges don't let you write to the *htdocs/* sub-directory, prefix your commands with *sudo*.

3. At the *sqlite>* prompt, create a new table to hold your data. In this example, the table is named *items* and it contains 3 columns, for item ID, item name and item cost. You can use standard CREATE TABLE syntax to create the table, and you can [learn more about SQLite's built-in datatypes here](#).

```
CREATE TABLE items (id INTEGER PRIMARY KEY, name TEXT, price REAL);
```

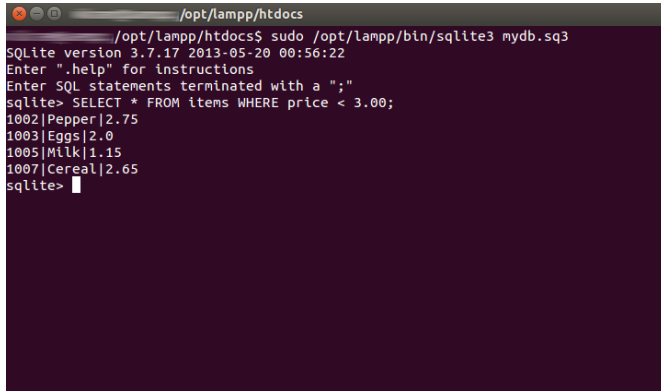

4. Add some data to the new inventory table using INSERT commands, as shown below:

```
INSERT INTO items VALUES ('1001', 'Salt', 3.15);
INSERT INTO items VALUES ('1002', 'Pepper', 2.75);
INSERT INTO items VALUES ('1003', 'Eggs', 2.00);
INSERT INTO items VALUES ('1004', 'Bacon', 7.25);
INSERT INTO items VALUES ('1005', 'Milk', 1.15);
INSERT INTO items VALUES ('1006', 'Strawberries', 8.73);
INSERT INTO items VALUES ('1007', 'Cereal', 2.65);
```

5. You can now also run a SELECT query on the data. For example, the query below returns all items that

cost less than \$3:

```
SELECT * FROM items WHERE price < 3.00;
```

```
/opt/lampp/htdocs$ sudo /opt/lampp/bin/sqlite3 mydb.sq3
SQLite version 3.7.17 2013-05-20 00:56:22
Enter ".help" for instructions
Enter SQL statements terminated with a ";"
sqlite> SELECT * FROM items WHERE price < 3.00;
1002|Pepper|2.75
1003|Eggs|2.0
1005|Milk|1.15
1007|Cereal|2.65
sqlite>
```

6. Once you're done using the database, exit it by typing `.quit` at the `sqlite>` prompt.

### IMPORTANT

The database file (in this example, `mydb.sq3`) contains all your tables and data, so you should remember to back it up regularly.

The previous steps discussed how to create and use an SQLite database using the command-line client. However, more often than not, you'll be using an SQLite database in combination with a PHP-powered Web application. XAMPP includes the PHP SQLite extension, so doing this is not very difficult at all.

To connect to your SQLite database and execute queries on it with PHP, use your text editor to create an example script named `sqlite.php` in the `htdocs` subdirectory of your XAMPP installation directory and fill it with the following code:

```
<?php
$db = new SQLite3('mydb.sq3');
$sql = "SELECT * FROM items WHERE price < 3.00";
$result = $db->query($sql);
while ($row = $result->fetchArray(SQLITE3_ASSOC)){
    echo $row['name'] . ' : $' . $row['price'] . '<br/>';
}
unset($db);
```

The first line of code creates a new SQLite3 object, using the `mydb.sq3` database file you created earlier. Then, the object's `query()` method is used to execute a SELECT query on the database, and the result object's `fetchArray()` method is used to iterate over the result set. Adding the `SQLITE3_ASSOC` parameter to the `fetchArray()` method tells PHP to return the results as an associative array, making it easy to access individual fields of the result set and display them on a Web page.

Once done, save your changes and ensure that your Apache server is running. Then, browse to <http://localhost/sqlite.php> to execute the script. You should see something like this:

Pepper: \$2.75  
Eggs: \$2  
Milk: \$1.15  
Cereal: \$2.65
